ACCESSION NR: AP4017398

S/0185/64/009/002/0196/0206

AUTHOR: Zapisochnyy, I. P.; Zhukov, I. G.; Garga, I. I.; Vuksty\*ch, V. S.,

TITLE: Vacuum monochromator for the investigation of optical excitation functions

SOURCE: Ukrayins'ky'y fizy\*chny'y zhurnal, v. 9, no. 2, 1964, 196-206

TOPIC TAGS: vacuum ultraviolet, vacuum ultraviolet spectroscopy, resonance level excitation cross-section, excitation cross-section, resonance radiation, ultraviolet monochromator, vacuum monochromator, electron beam excitation tube, mercury resonance lines

ABSTRACT: There are practically no data at present on the effective excitation cross sections of resonance levels of atoms, diatomic molecules and their ions of various multiplicity, owing to experimental difficulties in the vacuum ultraviolet region of the spectrum.

To obtain such data the authors have constructed a spectrophotometric set-up, consisting of three basic units: a vacuum monochromator of normal incidence with a one-metre (600 lines/mm) standard concave diffraction grating;

Card 1/4  
3

ACCESSION NR: AP4017398

highly monoenergetic electron beam excitation tubes; an electrophotometer using a secondary electronic multiplier (SEM) in a pulse counting regime for recording radiation in the vacuum ultraviolet region.

The monochromator was designed so that the refraction grating and rigidly attached input and output slits are always on the Rowland circumference. Transmission of movement in the vacuum is accomplished through bellows, while the kinematic system ensures linearity of the graduated graph throughout the working region (800-3500 Å).

The luminous vertical gas column in the excitation tube may be precisely set on the input slit under control of a distance gauge consisting of two telescopes, for which the possibility of moving part of the monochromator housing from the input slit is provided. This permits the maximum utilization of the light power of the monochromator (the loss in resolving power is negligible, since the intervals between the spectral lines are considerable for most objects).

The open type SEM, together with the voltage divider and the cathode repeater are located directly behind the output slit of the monochromator in a special shell. The pulse count is taken with the aid of a standard «Tulip» velocity meter.

Card 2/4

ACCESSION NR: AP4017398

The block diagram and the external appearance of the spectrophotometric set-up are shown in the appended drawings.

In conclusion, tentative data are given on the excitation functions of mercury lines  $\lambda=1850 \text{ \AA}$  (Hg I) and  $\lambda=1942 \text{ \AA}$  (Hg II).

Microchemical determination of magnesium. P. Yukujoy (Zavod.  
Lab., 1939, 8, 491--495).—Mg is pptd. as  $Mg(OH)_2$  and the latter  
titrated with 0.1N-HCl. J. J. B.

PROCESSING AND PROPERTIES INDEX	
ca	<p><b>Microchemical determination of magnesium.</b> P. Vukobratovic, <i>Zagreb. Lab. B.</i> 494-5(1960). -- The method is based on the vol. of HCl required to dissolve the Mg(OH)<sub>2</sub>. First, ppt. the Mg(OH)<sub>2</sub> with excess 0.1 N NaOH, boil the soln. for 3 min., dil. to 100 ml. with water, filter, and titrate the filtrate with 0.1 N HCl using Congo red as indicator to det. approx. NaOH used to ppt. the Mg. To a portion of the test soln. corresponding to 1.1-1.2 ml. of 0.1 N NaOH, add NaOH in excess (0.1-0.2 ml.), 1 ml. distd. water, and 1 drop of Congo red, heat carefully to boiling, keep in boiling water for 3 min., and centrifuge. Neutralize the excess NaOH in the supernatant soln. with 0.1 N HCl, mix the Mg(OH)<sub>2</sub> ppt. with small amt. of 0.1 N HCl until a blue color is produced, heat the soln., keep in boiling water, and add more HCl to dissolve the ppt. completely. Titrate the excess HCl with 0.1 N NaOH. Any free acid or NH<sub>4</sub> salt in the soln. to be tested should be removed by titration to a pH of 3-5.2 and by gentle ignition. Differences between captl. and actual values ranged from 0.00005 to 0.00003 mg./ml. soln.</p> <p>B. Z. Kamich</p>

PERIODICAL: Mashinostroitel', 1958, Nr 8, pp 33-34 (USSR)

ABSTRACT: Turning disc rollers (Figure 1) are used for cutting copper and copper-nickel pipes in order to avoid losses of material. The rollers are made from steel R9, R18, or from the alloyed steel KhVG. The roller is held in a special holder. The pipe is fastened by a pneumatic clamp chuck. The speed of cutting is 160 m/min. The new method increases the productivity 2.5 times. Losses of material have been cut; in every ton of cut pipes, 215 kg of metal are saved. There are 3 diagrams.

Progressive breakdown of solid insulators. In 1911, Phosphor 2, studied for a series of solid insulators including glass, oak, silk, mica and cable paper. The dependence of the breakdown p.d. on the no. of current impacts was studied for a series of solid insulators including glass, oak, silk, mica and cable paper. With glass the decrease in breakdown p.d. with the no. of current impacts is small. With cable paper it is large, and other insulators are intermediate. This decrease is due to the cumulative damage of each impact. The damage can be of chem. or mech. nature. The presence of surface charges as well as the use of a.c. makes progressive breakdown possible at lower voltages.

Ca

• The electrical breakdown of compressed nitrogen in a non-uniform electric field. I. M. Gaidman and B. N. J. Tech. Phys. U. S. S. R. 1, 407 (1931) (in English); J. Tech. Phys. (U. S. S. R.) 4, 1813 (1931) (in Russian). When the point electrode is pos. the point-plate breakdown voltage is a max. between 1 and 15 kV/cm., whereas when the point is neg. the voltage increases continuously with pressure. Irradiation by  $\gamma$ -rays widens the range and raises the max. of the breakdown voltage vs. pressure curve. P. H. Rathmann

Coremic high-frequency condensers. B. M. Val'ov  
G. I. Skanavi. *Bull. acad. sci. U.R.S.S., Ser. phys.* 8,  
191-9(1944).-- Ceramic elec. condensers are of 2 kinds:  
compensating and stable. The first have a neg. temp.  
coeff. (TK) of the dielec. const., which compensates the  
temp. coeff. of expansion; the second have TK approach-  
ing zero. Rutile, having a high dielec. const. and a large  
neg. TK, is used as the basic material for the manufact.  
compensating condensers. For stable condensers, masses  
having both pos. and neg. TK were investigated. Mg  
titanate has a low, pos. TK and a comparatively small  
dielec. const. Increasing the content of rutile in the  
compn. to 45% increases the dielec. const. to 1:1. Compos.  
of  $\text{TiO}_2$  and dolomite can be prep'd. that have a dielec.  
const. of approx. 80 and neg. TK of the order of  $10^{-5}$ .  
By combining compos. of  $\text{TiO}_2$  with  $\text{MgO}$  and with dolo-  
mite masses of any desired TK value can be obtained.  
The TK of the mixt. is the arithmetical mean of those of  
its components. Four references. W. R. Hean

A new form of barium titanate. B. M. Vul and I. M. Gol'dman (P. N. Lebedev Phys. Inst. Acad. Sci. U.S.S.R., Moscow). *Doklady Akad. Nauk S.S.S.R.* 60, 41-3 (1948). --BaTiO<sub>3</sub> prepd. from chemically pure BaCO<sub>3</sub> and TiO<sub>2</sub> (I) showed no ferroelectric properties (dielec. const.  $\epsilon \sim 50$ , little dependent on the temp.), in contrast to the compl. made from tech. materials (II) (e.g. from BaCO<sub>3</sub> contg. 0.46% CaCO<sub>3</sub>). X-ray examn. showed I and II to be structurally different, II having a tetragonal lattice with  $a = 3.98$ ,  $c = 4.04$  Å, I a lattice close to rhombohedral,  $a = b = c = 4.04$  Å, angle close to 90°. A sample of I, with  $\epsilon 65$ , was found to have a distorted cubic lattice; a sample of I with 1% SrCO<sub>3</sub> added (III), showed the usual BaTiO<sub>3</sub> lattice and had  $\epsilon 1035$ . Both I and III were found to contain some rutile. Evidently, in I, Ti ions are deprived of the freedom of displacements within the O<sub>6</sub> octahedrons. Ferroelectric. BaTiO<sub>3</sub> is easily obtained from I by adding to it about 2% Al<sub>2</sub>O<sub>3</sub>; such samples had a tetragonal lattice with  $a = 3.98 \pm 0.01$  and  $c = 4.02 \pm 0.01$  Å. N. Thon

The nature of the piezoelectric properties of barium titanate. B. M. Vul', *Pamyat Sergeya Ivanovicha Aristova, Akad. Nauk SSSR*, 1952, 319-23. The piezoelectric properties of  $\text{BaTiO}_3$  can be explained on the basis of the interaction between deformation and polarization taking place in this material below the Curie point. Mech. action changes the existing deformation and simultaneously the polarization, which manifests itself as direct piezoeffect in the form of free elec. charges on the electrodes of the piezoelement. Elec. action changes the magnitude of the acquired polarization and the deformation of the elementary cells in the crystallographic lattice, which manifests itself as reverse piezoeffect, i.e. as variation of the dimensions of the whole piezoelement. On the basis of these assumptions formulae are developed for the calcn. of the piezoeffects. Piezoeffects were calcd. for monocrystals at temps. where  $\text{BaTiO}_3$  still retained tetragonal structure. These calcd. piezoeffects corresponded to the exptl. values found by statistical measurements on polarized polycryst. samples. N. Goldowski

Title : Capacity of transitory layers in semi-conductors

Periodical : Dokl. AN SSSR, 96, Ed. 2., 257 - 259, May 1954

Abstract : A transitory layer between parts of a semi-conductor having different degree of conductivity expands to the boundaries of space charges where the intensity of the electrical field can be considered zero. The boundaries of space charges may vary under the effect of the intensity applied from without. The differential capacity can easily be measured thus enabling to determine the thickness of the transitory layer in relation to the constant intensity applied from without. Title : ~~Dielectric properties of the transitional layers in~~ Dielectric properties of the transitional layers in semiconductors

Periodical : Zhur. tekhn. fiz. 25, 3-10, Jan 1955

Abstract : Transitional layers are created in semiconductors in connection with sharp changes in the concentration of the admixtures (impurities) serving as sources of electrons or as their sinks (i.e. as donors or acceptors). The role of transitional layers between two semiconductors with different types of conductivities was theoretically treated for the first time by B. I. Davydov (ibid. 8, 1938), and experimentally investigated by A. V. Ioffe (ibid. 18, 1948); a detailed survey of the modern theory of solid rectifiers and contact semiconductors was given by A. I. Gubanov (ibid. 23, 1953). In most works the principal task has been the clarification of the process of rectification and therefore the effects of the joint action in the transitional layer of diffusion and electrical conductivity have been considered. In the present work the author considers the capacity, resistance, and dielectric losses of the transitional layer under the condition where the contact difference of potentials is much larger than  $kT/q$  ( $q$ : electron charge). 9 ref.

Title : Influence of Polarization Conditions on the Piezo Properties of Barium Titanate

Orig Pub : Zh. tekhn. fiziki, 1956, 26, No 5, 958-962

Abstract : The effect of the intensity of the polarizing electric field  $E$  and of the temperature  $T$  on the piezo-modulus  $d_{33}$  of ceramic  $BaTiO_3$  was investigated. It is shown, that the polarization of thick specimens can be produced at lower values of  $E$  and at higher values of  $T$ . The closer the polarization temperature is to the Curie temperature, the less the value of  $E$  required for the polarization.

To orient the fundamental part of the domains in the interval of the rapid growth of the spontaneous polarization ( $6 - 7^\circ$  below the Curie point),  $E$  must not be less than 5 kv/cm for any values of  $T$  of the polarization.

On the Breakdown of Transition Layers in Semiconductors.

Zhurn.techn.fiz, 26, fasc.11, 2403-2416 (1956)

Issued: 12 / 1956

CARD 1 / 2

PA - 1678

The principal forms of breakdown in electron-hole-transitions. The disruptive voltage of germanium diodes at increased temperatures diminishes considerably with increasing temperature. Therefore thermal ionization plays the most important part among the processes which promote breakdown. However, in the case of diodes of low resistance germanium, the disruptive voltages depend in a wide range of temperature only little on temperature and increase with rising temperature. With these electrodes the increase of the number of electrons mainly takes place in form of collision ionization. Thus it is possible to distinguish between a thermal and a dielectric form of breakdown both in the case of semiconductors and in that of dielectrics. The diodes of germanium with an increased specific resistance (order of magnitude 10 ohm.cm) have a smaller disruptive voltage for parallel current than for current pulses. By improving heat transfer it is possible to increase disruptive voltage. However, the dependence of disruptive voltages on temperature and on the conditions of heat transfer is not so marked in the case of these diodes as in the case of purely thermal breakdown. It may be that breakdown is brought about by the simultaneous effect of thermal- and collision ionization ("thermoelectric breakdown").

Zurn.techn.fiz, 26, fasc.11, 2403-2416 (1956) CARD 2 / 2

PA - 1678

Thermal breakdown: At first the bases of the elementary theory are recalled to memory after which they are augmented by taking the following additional factors into account: Influence exercised by the resistance R which is independent of temperature; influence of additional amperage which is independent of voltage; influence of additional losses which are independent of counter-voltage; influence exercised by the heat conductivity of the crystal.

Electric breakdown: was found to occur in pure form in the case of parallel voltage only with diodes of low-resistance germanium, but in the case of pulse-like tests it was found in germanium of any resistance. Electric breakdown is caused on the occasion of electron-hole transitions as well as in gases by collision ionization. The computation of the conditions of breakdown is sketched out.

Thermoelectric breakdown: Already before thermal breakdown is about to occur it is possible that the amperage increases considerably because of ionization if field strengths in the electron-hole-transition are high. This increases heating of the diode and thus also thermal ionization in it. The electrons liberated by thermal ionization participate in collision ionization, and, if intensity is sufficient, the common effect exercised by thermal- and collision ionization may lead to the destruction of the state of equilibrium, and to breakdown.

TITLE

On the transformation of the energy of  $\beta$ -particles into electric energy in germanium crystals with P-N transitions. (O preobrazovanii energii  $\beta$ -chastits v elektroenergiyu v kristallakh germaniya s P-N-perekhodom. - Russian) Atomnaya Energiya 1957, Vol 2, Nr 6, pp 533-537 (USSR).

PERIODICAL

ABSTRACT

In 1955 the authors carried out experiments in the determination of the degree of efficiency of the transformation mentioned in the title. The P-N transitions were obtained by the melting of indium.  $Sr^{90}$  -  $Y^{90}$  preparations served as sources of  $\beta$ -particles. The total activity of the primary radioactive preparations amounted to 50, 100, and 200 millicuries. As source of  $\beta$ -particles strontium sulphate tablets with 50 and 100 millicurie and strontium carbonate tablets with 200 millicurie were used. A diagram shows the  $\beta$ -spectra of these sources. Also measurements during irradiation of a semiconductor with artificially accelerated electrons (400 to 1150 keV) were carried out. The degree of efficiency

 Issued: 2 / 1957

CARD 1 / 2

PA - 1944

On the boundary of the electron-hole transition on the surface of the semiconductor breakdown is complicated by a boundary effect. The surrounding medium is able to limit breakdown voltage considerably if on the surface of the diode "overlapping" (i.e. a surface discharge at a voltage that is lower than the breakdown voltage of the electron-hole transition in the interior of the semiconductor) occurs. In the case of constructions encountered in practice the electron-hole transition is located in a gaseous medium at atmospheric - or lower - pressure. For gaseous media there exists a minimum breakdown voltage below which no electric breakdown can occur in this gas. For air the minimum breakdown voltage amounts to  $U_{min} \approx 330$  V and to this belongs also the value  $pd \sim 6$ . Here  $p$  denotes the pressure in mm<sup>torr</sup> and  $d$  - the distance between the electrodes in mm. In the case of diodes in which the breakdown voltage of the electron-hole transition in the interior of the sample is less than  $U_{min}$ , overlapping can therefore not occur at all gas pressures. On the other hand, overlapping can prevent total utilization of the possibilities of the diode in the case of diodes in which the breakdown voltage of the electron-hole transition is more than  $U_{min}$ .

Zhurn. techn. fis. 27, fasc. 1, 211-212 (1957)

CARD 2 / 2

PA - 1944

The measurements carried out by the authors showed that what has just been said is true. In the case of diodes with a breakdown voltage of less than 300 - 400 MeV this breakdown voltage remains constant at any air pressure. Measurements were carried out on diodes which were not mounted in cartridges, and also in such diodes into the cartridges of which holes had been bored.

In diodes with an average breakdown voltage of 400 MeV at normal pressure a surface discharge occurs at diminished air pressure approximately at those values of  $p_d$  which correspond to the voltage  $U_{min}$ . In the case of a further decrease

of air pressure the surface discharges cease. Frequently the properties of the diode are deteriorated considerably by the surface discharges. On the occasion of the practical construction of high-voltage diodes it is obviously necessary, when selecting the medium surrounding the electron-hole transition, to take care that overlapping voltage is greater than the breakdown voltage of the electron-hole transition in the interior of the semiconductor.

The above is a translation of this short report.

TITLE: On the Edge Breakdown of p-n Junctions in Germanium (O krayevom proboye p-n-perekhodov v germanii).

PERIODICAL: Zhurnal Tekhn. Fiz., 1957, Vol. 27, Nr 10, pp. 2189-2194 (USSR).

ABSTRACT: The breakdown potentials of diffusion junctions (transition) and melted-in  $p^+n^-$  and  $n^+p^-$  junctions were measured in air and in media with an increased dielectric constant. It is shown, that the dielectric constant has a marked influence on the breakdown potentials of the  $p^+n^-$  junctions and that it plays an important rôle in the breakdown of the  $p^+n^-$  and of the diffusion junctions. The observed phenomena can be explained with the assumption, that the surface of the germanium carries a positive charge and that the medium determines the effectiveness of the surface charge. There are 5 figures, 1 table and 3 Slavic references.

TITLE:

On the Theory of Electron-Hole Transitions in Semiconductors  
(K teoriia elektronno-dyrochnykh perekhodov v poluprovodnikakh)

PERIODICAL:

Zhurnal Tekhnicheskoy Fiziki, 1958. Vol. 28, Nr 4, pp. 68-69  
(USSR)

ABSTRACT:

Reference is made here to the formula  $\frac{d^2u}{dx^2} - \text{sh } u = -f(x)$  (1.1) by W. Shockley (Ref. 1). This approximate equation is here investigated under the following assumption: Instead of the boundary case studied by Shockley, where the space charge is only produced at the expense of ionized admixtures, it is assumed here that  $\text{sh } u = u$ , i.e. that the equation (1.1) is investigated in the form of

$$(1.4) \dots \frac{d^2u}{dx^2} - u = -f(x)$$

with maintenance of the boundary condition (1.3), that is to say, that  $u$  in the case of  $x = \pm\infty$  is limited. The solution of (1.4) with the condition (1.3) in the form of (4.3) is derived. Now it is determined under which conditions the solution (4.3) can approximately replace the exact solution (1.1) under the

Card 1/2

On the Theory of Electron-Hole Transitions in Semiconductors 57-28.4.1/33

condition (1.3). It is shown that this is the case in the entire domain of  $-\infty < x < \infty$ , when  $A$  (a nondimensional positive constant) is sufficiently small. On that occasion (a dimensional positive constant) can be of any arbitrary value. In the case of a small excess concentration of the admixtures the potential quantity remains small also in the case of any  $x$ -value. Therefore  $\frac{2h}{u} \ll 1$ , and equation (1.4) is everywhere a good approximation for equation (1.1). In the modern semiconductor devices  $A \gg 1$ . Therefore other conditions for the usefulness of the linear approximation which hold in the limited interval spaces also when  $A \gg 1$  are examined for the domain  $-\alpha < x < \alpha$ ... (6.1) and  $-\alpha < x < -\alpha$ ... (7.1). The equations (6.7) for the first and (7.7) for the second case are obtained. From these follows that they - (6.7) or (7.7) - according as  $m \ll 1$  or  $m \gg 1$  serve as criterion for the usefulness of the linear approximation (4.3) instead of the exact solution (1.1) with the limiting conditions (1.3) in the domain of  $-\alpha < x < \alpha$  ( $m > 0$ ). There is 1 reference, 0 of which is Soviet.

Landsberg-Markhanova, Candidate of Physical and Mathematical Sciences; and G. P. Motulevich (Secretary), Candidate of Physical and Mathematical Sciences.	
	PURPOSE: This book is intended for physicists and researchers engaged in the study of electromagnetic radiations and their role in investigating the structure and composition of materials.	
	COVERAGE: The collection contains 30 articles which review investigations in spectroscopy, optics, molecular optics, semiconductor physics, nuclear physics, and other branches of physics. The introductory chapter gives a biographical profile of G. S. Landsberg, Professor and Head of the Department of Optics of the Division of Physical Technology at Moscow University, and reviews his work in Rayleigh scattering, combat gases, spectral analysis of metals, etc. 25 personalities are mentioned. References accompany each article.

TITLE:

Investigation of Large Germanium Rectifiers

PERIODICAL:

Elektrichestvo, 1959, Nr 10, pp 21-26 (USSR)

ABSTRACT:

This article presents the results of an investigation of large germanium rectifiers of the VG type which were made by the Vsesoyuznyy elektrotekhnicheskiy institut im. Lenina (All-Union Electrotechnical Institute imeni Lenin) (Ref 1). Figure 1 shows the section of a VG-10 rectifier. The dependence of the rectified currents upon voltage and temperature was determined at a temperature maintained constant by means of a thermostat. The saturation current was determined by measuring the direct and backward current at voltages of

$$U \approx \frac{kT}{q} \text{ and according to the}$$

backward branch of the static characteristics (Ref 4).  $U$  denotes the voltage in the p-n transition of the rectifier,  $T$  the absolute temperature,  $k$  the Boltzmann constant, and  $q$  the elementary charge. The backward branch of the static characteristics was plotted at two values of heat emission. The investigation yielded

Card 1/3

is assumed to be the only reason

## Investigation of Large Germanium Rectifiers

SOV/105-59-10-4/25

the following results: (1) The rectified current  $I_d$  exhibits a sufficiently large section on the static characteristics for which formula (1) holds. The deviations from this formula occurring at increased current densities result from the occurrence of the electron component of the rectified current, which in turn leads to an additional voltage drop and additional losses. The temperature coefficient of the rectified current in the experiments is in good agreement with that of calculations. It is about 3% for the group of rectifiers under discussion. (2) The saturation current calculated according to the formula (see Table 3) is somewhat higher than those obtained by experiment. (3) The differential capacity of p-n transitions of the investigated rectifiers is inversely proportional to the square root of the voltage applied. This indicates the gradual character of the p-n transitions. (4) The backward currents increase monotonously with increasing backward voltage. (5) The pulsed breakdown voltages of the individual rectifiers approximately agree with those to be expected from the specific resistance of germanium foils. Formula (11) yields excessively high breakdown voltages if the heating of the rectifier is assumed to be the only reason

Card 2/3

Investigation of Large Germanium Rectifiers

SOV/105-59-10-4/25

for the increase in the backward current. Formula (13) holds for the overheating of the diode when breakdown occurs, which approximately agrees with the experimental results. There are 7 figures, 6 tables, and 7 references, 4 of which are Soviet.

TITLE:

Quantum-mechanical Semiconductor Generators and -Amplifiers of Electromagnetic Oscillations

PERIODICAL:

Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1959, Vol 37, Nr 2(8), pp 587-588 (USSR)

ABSTRACT:

In the present "Letter to the Editor" the authors discuss the possibility of using the electron transitions between the conductivity zone (valence zone) and donor (acceptor) impurity levels of a semiconductor for the production of electromagnetic radiation (like in a molecular generator). For the realization of semiconductor generators and -amplifiers it is necessary to provide for such a distribution of electrons (holes) in the conductivity zone (valence zone) that the effective temperature of the conductivity electrons (holes) is negative with respect to the ionized donors (acceptors). Such a semiconductor has negative frequency losses in the case of transitions of electrons (holes) from the conductivity (valence) zone to impurity levels. If such a semiconductor is irradiated with electromagnetic waves, the latter may be amplified; if certain conditions (self-excitation)

Card 1/3

Quantum-mechanical Semiconductor Generators and  
-Amplifiers of Electromagnetic Oscillations

SOV/56-37-2-54/56

are satisfied, such a device may work as generator. In order to attain negative temperatures, a special impurity ionization mechanism is suggested. This state with negative temperature is maintained during the relaxation time of electrons (holes) with the impurity levels. If the number of impurities is small compared to the number of atoms in the crystal lattice, the life time of the conductivity electrons (holes of the valence zone)  $\tau_2$  is large compared to the time  $\tau_1$  between the collisions of electrons (holes) with the lattice.  $\tau_2$  may be regulated by the impurity concentration. During the period  $\tau_2$  the system may be used as a generator or as amplifier of electromagnetic oscillations. A reduction of the surface

SOV, 20-129-1-16/64

AUTHOR: Vul, B. M., Corresponding Member, AS USSR

TITLE: On p - n Transitions at Low Temperatures

PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 129, Nr 1, pp 61 - 63 (USSR)

ABSTRACT: At sufficiently low temperatures, the concentration of the electrons in the conduction zone and the concentration of the holes in the valence zone becomes very small in comparison to the concentration of the admixture, assuming, that  $W_1 \ll kT$  holds for the ionisation energy of the admixture in the semiconductor ( $k$  = Boltzmann constant,  $T$  = absolute temperature). At low temperatures the effect of the electrons and holes on the formation of space charge of the p - n transition may be neglected. In this case the following equation for the potential distribution in a step-like p - n-transition in dimensionless quantities is obtained for the one-dimensional problem with lacking degeneration:

$$\frac{d^2 \psi}{d\xi^2} = - \frac{v_d}{1+e^{-\beta+\psi}} - \frac{v_a}{1+e^{-\beta-\psi}} \quad \text{if } \xi \gg 0$$

Card 1/4

66470

SOV/20-129-1-16/64

On p - n Transitions at Low Temperatures

$$\frac{d^2\psi}{d\xi^2} = - \frac{v_d'}{1+e^{-\beta+\psi}} - \frac{v_a'}{1+e^{-\beta-\psi}} \quad \text{if } \xi \leq 0. \text{ The units are}$$
  
 defined as follows: Unit of potential  $\psi = kT/q$ , unit of length  $\xi =$  Debye length, unit of concentrations  $v_d'$  and  $v_a'$  ( $v_d'$  and  $v_a'$ ) of the donors, and the acceptors respectively in an electronic semiconductor (hole-semiconductor) = intrinsic concentration of the electrons  $n_i$ .  $\epsilon$  denotes the dielectric constant,  $q$  the unit charge. Furthermore it holds that  $\beta = (g-2W_1)/2kT$  ( $g =$  width of the forbidden zone of energies) and  $W_1$  is assumed to be equal for both donors and acceptors. The first terms of the above described two equations correspond to the ionized donors and the second terms to the ionized acceptors. These terms depend on the distribution of the potential in the present case. It was found:

$$\frac{v_d - v_a}{v_a} = \frac{\alpha(e^{v_d'} - e^{-\psi_d'})}{1 + \alpha e^{-\psi_d'}}. \text{ Here it holds that } \alpha = e^{-\beta} \text{ and } \psi_d$$

Card 2/4

denotes the value of the potential  $\psi$  for  $\xi \rightarrow \infty$ . In germanium,

66470

On p - n Transitions at Low Temperatures

SOV/20-129-1-16/64

$\psi_d = \beta$  for  $\xi \rightarrow \infty$ ,  $\psi_a = -\beta$  for  $\xi \rightarrow -\infty$ ,  $\psi_d - \psi_a = 2\beta$ , is valid with great accuracy. The solution of the first of the above-mentioned two equations runs as follows:

$\frac{d\psi}{d\xi} = \left[ \alpha - 2\nu_d \frac{e^\psi}{1+e^{\psi-\beta}} + 2\nu_a \ln(e^{-\beta} + e^\psi) \right]^{1/2}$ . By taking into account the condition  $d\psi/d\xi = 0$  for  $\xi \rightarrow \infty$  it is found that

$\frac{d\psi}{d\xi} = 2^{1/2} [\nu_d \beta - \nu_d \psi + \nu_d \ln(1+e^{\psi-\beta}) + \nu_a \ln(e^{-\beta} + e^\psi)]^{1/2} \approx [2\nu_d(\beta - \psi)]^{1/2}$ . In similar way one gets

$\frac{d\psi}{d\xi} = [2\nu_a'(\beta + \psi)]^{1/2}$  for  $\xi < 0$ . After some steps of computation:

$\psi(\xi) = \beta - (\sqrt{2\beta} - \sqrt{(\nu_d/2)\xi})^2$  is obtained. Therefore the complete potential difference belongs practically to the range  $\xi > 0$  for  $\nu_a' \gg \nu_d$  and the width of the p - n transitions extends from  $\xi = 0$  to that value  $\xi = \xi_a$  for which  $\psi = \beta$ . For the potential

Card 3/4

difference at the transition, caused by diffusion,

66470

SOV/20-129-1-16/64

On p - n Transitions at Low Temperatures

$U_d = (g - 2W_1)/q \sim g/q$ . For  $g$  measured in eV  $U_d$  in V is numerically equal to the forbidden zone of energies. The width of the p - n transition amounts to

$h = (g - 2W_1)^{1/2} \epsilon^{1/2} / q(2\pi N_d)^{1/2}$  in the absence of external voltage.

At low temperatures most of the admixtures are almost completely ionized in the zone of the p - n transition. The results of the present paper were confirmed by investigations of the capacity of p - n transitions at low temperatures. There are 4 Soviet references.

TITLE:

Impact Ionization and Tunnel Effect in Semiconductors

PERIODICAL:

Fizika tverdogo tela, 1960, Vol. 2, No. 11, pp. 2961-2967

TEXT: The present paper offers a discussion, based on theory, of the impact ionization in p-n junctions, of low-temperature breakdown, and of the tunnel effect in p-n junctions. The first publications in this field are by A. F. Ioffe. It is pointed out that the elementary theory of impact ionization in semiconductors is in a certain way simpler than in gases, this being chiefly due to the fact that in gases the two partners concerned - electrons and ions - have a very different mobility, whereas it is practically the same in semiconductors (electrons and holes). On the basis of the Townsend theory, the condition  $\int_0^h \alpha dx = \ln k/(k-1) = \text{const}$  must be satisfied for the breakdown of a p-n junction;  $k = \beta/\alpha$ ;  $\alpha$  - coefficient of impact ionization of an electron,  $\beta$  - that of a hole. The maximum electric field strength  $E_{\text{max}}$  at the junction is equal to  $2u/h$ , where  $u$  is

Card 1/43

86450

Impact Ionization and Tunnel Effect  
in Semiconductors

B006/B060

the voltage at the junction and  $h$  the thickness of the junction layer. The  $\alpha$ -values obtained theoretically and experimentally are intercompared in tables for different  $E$ -values. The following was obtained for germanium:  $\alpha = 10^{-25} E^{5.5} \text{ cm}^{-1}$ , and  $\beta = 2 \cdot 10^{-25} E^{5.5} \text{ cm}^{-1}$ , while for silicon  $\alpha = 1.4 \cdot 10^{-22} E^{4.7} \text{ cm}^{-1}$ , and  $\beta = 0.31 \cdot 10^{-22} E^{4.7} \text{ cm}^{-1}$ . Hence the dependence of impact ionization on the field strength is more strongly marked in germanium than in silicon. At temperatures near the absolute zero point, impact ionization may be also observed in homogeneous semiconductors. If the most favorable conditions for impact ionization are provided in, say, germanium, i.e., low ionization energy (which is only about  $10^{-2} \text{ eV}$  for impurities of the 3rd and the 5th group in Ge) and a large mean free path an impact ionization may be brought about already at exceedingly low field strengths (some  $\text{V/cm}$  in Ge). The current density as a function of  $E$  for homogeneous p-type germanium is shown in Fig. 2, based on data by Zavaritskaya. The curve shows that impact ionization appears at about  $5 \text{ V/cm}$ , while at  $20 \text{ V/cm}$  the impurities are practically ionized completely. The ionization of impurities took place solely by holes at this low-temperature breakdown (in n-type, analogously, by electrons only).

Impact Ionization and Tunnel Effect  
in Semiconductors

S/181/60/002/011/040/042  
B006/B060

The possibility is finally discussed of explaining the breakdown of a p-n junction by the tunnel effect. The position of the Fermi levels and the characteristics of an Esaki diode are discussed in great detail. Fig. 3 shows the position of the Fermi levels for a p-n junction in a degenerate semiconductor with thermal equilibrium (a), a maximum direct current (b), and a minimum direct current (c). Fig. 4 illustrates the dependence of the current on the voltage at a tunnel diode on the basis of data by A.P. Shotov. I. I. Ivanchik calculated a p-n junction in a degenerate semiconductor. L. V. Keldysh and V. A. Chuyenkov are mentioned. There are 4 figures, 3 tables, and 11 references: 8 Soviet, 1 British, and 2 US.

Radio Industry), and in 1940 he began his activities at the Institute of Physics imeni B. N. Lebedev of the AS USSR, first in the capacity of senior scientific worker, and later as deputy of the Head of the elektrofizicheskaya laboratoriya (Electrophysical Laboratory), and since 1954 as Head of the Laboratory of the Physics of Dielectrics, which became the leading laboratory in this field of the Soviet Union. The first works (1931-1935) of the deceased dealt with the high-voltage insulation of electrical machines. His method of removing the corona, and his method of testing insulation were used in industry. Skanavi became Candidate of Physical and Mathematical Sciences in 1937. Many of his works dealt with the dielectric losses and with polarization in glasses. Skanavi drafted the theory of relaxative losses, and discovered the neutralization- and crystallization effect of loss reduction. During the war he investigated polycrystalline dielectrics at the Institute of Physics, produced new dielectrics with a high dielectric constant, and developed a theory, which explains the high dielectric constant of crystals. It was upon these works that the Doctor's dissertation defended by him in 1946 was based. For the industrial production of ceramic capacitors developed by him, he was awarded the Stalin Prize

Card 2/3

Georgiy Ivanovich Skanavi (Deceased)

in 1952. In recent years Skanavi, assisted by the collaborators of his laboratory, produced dielectrics with a particularly high dielectric constant: the strontium-bismuth-titanates. In 1958 the first strontium-titanate single crystals were obtained at his laboratory. During the investigation of the electric strength of dielectrics the photoconductivity of KBr crystals stimulated by high voltage pulses was discovered. Further, Skanavi delivered the glass substances known as "pyroceram" <sup>15</sup> with finely disperse crystalline phase and a new class of electrets. Besides his scientific activities, Skanavi was for several years the Head of the works laboratory of a radiotechnical factory in Moscow. He published more than 70 scientific works, among them the monograph "Fizika dielektrikov" in two volumes. For several years Skanavi was the scientific secretary of the Institute of Physics, and Member of the Byuro otdeleniya fiziko-matematicheskikh nauk AN SSSR (Bureau of the Branch of Physical and Mathematical Sciences of the AS USSR). Since 1944 Skanavi has been Member of the Communist Party of the Soviet Union, and since recently also Secretary of the Party Committee of the Institute of Physics. There are 1 figure and 55 Soviet references.

TITLE: Impurity Conductivity of Germanium at Low Temperatures

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 135, No. 6,  
pp. 1361-1363

TEXT: At temperatures  $T \ll \epsilon_i/k$ , where  $\epsilon_i$  is the impurity ionization energy and  $k$  the Boltzmann constant, the electrical conductivity of semiconductors is very low. If the field strength is increased, the impact ionization increases, because the mean free path of the carriers is relatively great at low temperatures. As the impurity ionization energy is low (0.01 eV for the indium-doped p-type germanium considered here), impact ionization starts already at field strengths of some V/cm. The lower the temperature, the lower is the fraction of thermal ionization, as follows from the dependence of current density on field strength shown in Fig. 1. At the temperature of liquid helium, the hole concentration may be

Card 1/2

described by:  $p = \frac{s(N_a - N_d) - rN_d}{r + s}$  (1), where  $s$  is the mean ionization probability,  $r$  the mean recombination probability,  $N_a$  the acceptor concentration, and  $N_d$  the donor concentration. As the increase in  $r$  with an increase of electron energy is much slower than that of  $s$ , the free hole concentration in the range of pre-breakdown field strength is determined largely by the exponential growth of the ionization rate. The drift rate as a complex function of field strength is discussed, and it is found that at high field strengths the sharp decrease in mobility at helium temperatures is connected with the occurrence of a large quantity of charge centers. Thereby, the fraction of Coulomb scattering in the total number of collisions per unit time increases. The authors thank V. A. Chuyenkov for a discussion. TITLE: Capacity characteristics of p-n junctions

PERIODICAL: Fizika tverdogo tela, v. 3, no. 1, 1961, 204-205

TEXT: The present paper deals with the derivation of some formulas for calculating the capacity of p-n junctions. The capacity of a p-n junction depends on the ionized-impurity distribution in it. For clarifying the principal relations, it suffices to study the simple case of a plane junction, in which the one side, e.g., the p-type, has such a low resistance that the entire resistance may be ascribed to the n-type side. In this case, the potential distribution in the junction may be described by the Poisson equation  $d^2\psi/dx^2 = -4\pi q/\epsilon$ , where  $q = f(x)$  is the volume charge density, and  $x$  is the distance of the point of reference in the n-type region from the junction surface. With the boundary conditions  $\psi(0) = \frac{d\psi}{dx}\bigg|_{x=h} = 0$ ,  $U = \psi(x)_{x=h} = \frac{4\pi}{\epsilon} \int_0^h xf(x)dx$  is the solution,
